

LINUX FOR PROGRAMMER

Linux is an open-source Operating System and a flavor of UNIX. An Operating System is software that communicates between Hardware and Software of Computer. Operating System of Unix/Linux works on Kernel. UNIX is multi-user as well as multitasking because several people can use a Unix Computer at the same time and user can run multiple programs at the same time. Linux is released under General Public License (GPL) that means people can read the source code and can also modify and share. Linux is the basic requirements of the every IT initiatives like cloud computing, security and containers. Linux has grown as the people started understanding of the importance and working system of Linux. It is very easy to use as it comes in GUI form that makes easy to use for everyone. Linux has many distributions of Linux like Ubuntu, fedora, kubuntu, Arch Linux, Mageia and many more. Different distributions for different people according to requirements.

WHY LINUX OVER WINDOWS

1. Open Source: -

Linux is an open source and also, we can look and analyze the source code of Linux.

2. Secure:-

Security is an important factor for a person. Linux is not as vulnerable as Windows and a lot more secure. You don't need any Antivirus in Linux whereas you have to buy Antivirus Program every year to be secured from hackers.

3. Perfect for programmers:-

Linux offer large range of applications for programming purposes. Linux also offer predefined libraries for developers. Linux has ability of bash scripting which is one of the most important reasons programmer should prefer using Linux OS. It also supports SSH which helps manage the server quickly.

4. Software updates:-

Linux is updated frequently, and much faster. Whereas, In Windows Microsoft update only when receives major issues and need to be fixed.

5. Variety of Distributions:-

Windows doesn't have any flavor, whereas, Linux has large variety of distributions. You can use different Linux according to needs or requirements.

E.g.:- There is Linux distribution for hacker, for programmers, etc.

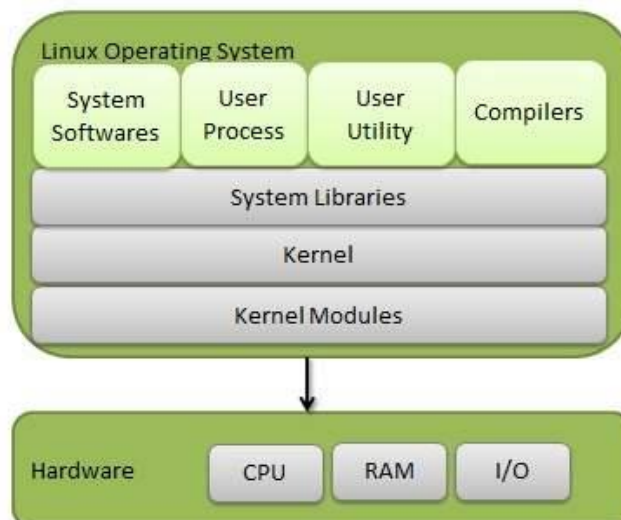

6. Reliability:-

You need to reboot every time you install or uninstall or update any software in Windows. Whereas, In Linux you don't need to reboot every time.

STRUCTURE OF LINUX:-

Linux operating system is structured in the same way of other operating system i.e.:-

- system software/user process/user utility/compilers
- system Libraries
- Kernel
- Kernel Modules

system software/user process/user utility/compilers

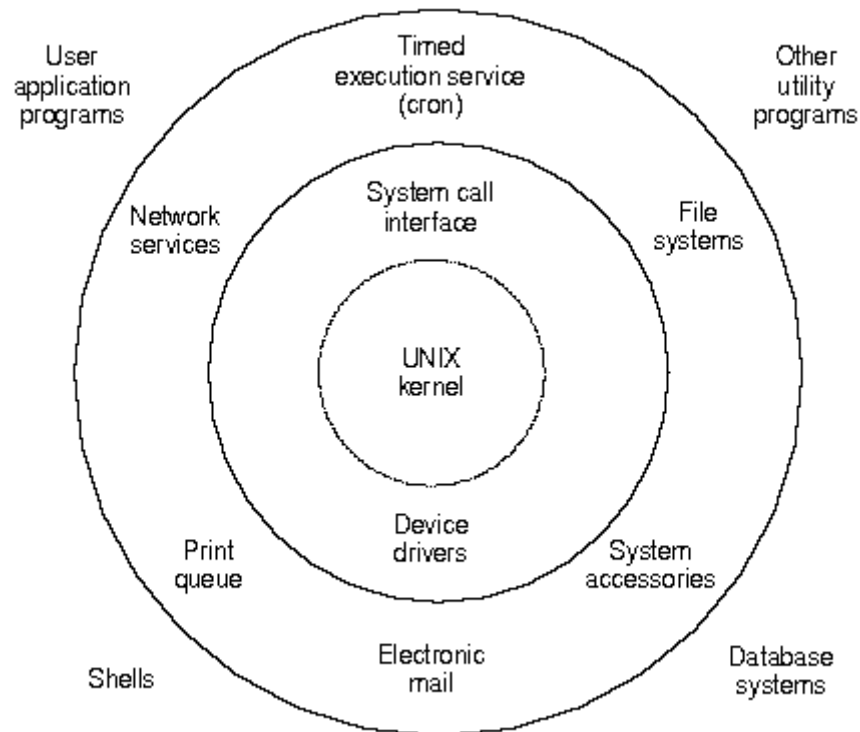

Software for everyone (users) written and published by GNU Project. This is the upper layer which is seen in GUI form by users.

System Libraries - Libraries are pre-compiled piece of code to communicate with the kernel. These libraries help in accessing kernel features which will be triggered to perform tasks. It makes easier for the programmer to build an application.

Some of the libraries in Linux are - libs, glibc, libcurl, libcrypt and many more.

1. libc is the standard C library
2. glibc is GNU version of standard C library
3. libcurl is multi-protocol file transfer library
4. libcrypt is the library used for encryption, hashing and encoding

Kernel- The heart of the Operating System which interacts with the hardware and lets the tasks perform like device management, memory management and process management.

Interaction with kernel is done through Shell. Shell is a command line user interface. Shell translates the command from user into the language understood by kernel and vice-versa. Shell is

also a scripting language used by Operating System to control the executions of the system using Shell Scripts.

Hardware

Physical equipment like keyboard, mouse and other physical devices connected with your system.

Once you enter the Unix/Linux Operating System, Open Terminal or press "CTRL+ALT+T" for terminal to appear and start working. On Terminal you will notice dollar (\$) or hash (#) symbol on the left. This indicates the type of user you are.

Dollar Sign (\$) indicates that you are a normal user and don't have administration permission. You are using this Operating System as a guest.

Hash Sign (#) indicates that you are the system administrator i.e. in root mode and you have all permissions in the system.

E.g.: If it's (\$) and try to change the password, you won't be allowed to do so but if you switch to root mode i.e. (#) you will have permission to do so.

You can switch from guest to user by

```
$ su root
OR
$ sudo root
```

To switch to any user by

```
$ su <username> OR $ sudo <username>
```

You can run root commands from user by using "sudo" before command

e.g.

```
$ sudo command
```

You can check for the user you are in by

```
$ whoami
```

To list all the users in System by

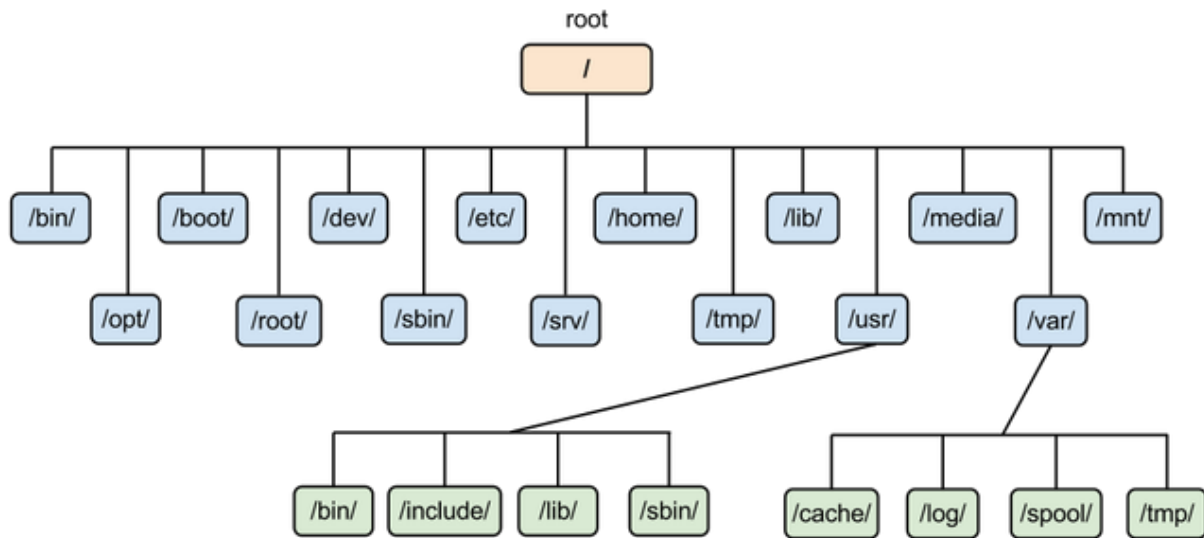

```
$ users
```

To check the manual of "ls" command

```
$ man ls
```

FILE SYSTEM OF LINUX

File System is a tree like structure of directories. Data in Linux is organized in files and files in directories. Linux follow File system Hierarchy Standard (FHS). It explains the content and location of the files and directories. you can know about your file system FHS, by command "man hier" this will open the manual of hierarchy of file system.

There are 3 basic types of files in Linux/UNIX OS:-

1. Directories - Directories are equivalent to the Folders in Mac OS or Windows. It stores both special and ordinary files.
2. Special Files - Some files which provide access to hardware like hard drives, modems, Ethernet and CD-ROM.
3. Ordinary Files - Files on the system that contains data, text or program instructions.

DIRECTORIES OF LINUX

Directories are the folders in Linux organized in tree structure. The tree has single root node shown by slash (/).

To create a new directory

```
$ mkdir mynewdir
```

To create a directory in another directory

```
$ mkdir /temp/aarju_dir/new_direct
```

To remove a directory

```
$ rmdir mynewdir
```

Renaming directory

```
$ mv old_dir new_dir
```

PATHNAME

To know the current path you are in

```
$pwd
```

There are 2 types of pathname in Linux Absolute and Relative.

Absolute - path begin with a slash (/)

Eg -

```
$ pwd
/etc/passwd
```

Relative - start with your current working directory name and never with slash (/)

Eg -

```
$ pwd
aarju_files/notes
```

To list all the files in directory

```
$ ls /usr/share
```

This will list all files in share directory in usr

Commands for Linux File

To list the files in current directory

```
$ ls
```

To list the files in current directory with their information like permissions. This will list the files with their permissions and many more details.

```
$ ls -l
$ ls -la
```

To create a new file

```
$ touch file_name
$ cat > file_name
```

To remove a file

```
$ rm file_name
```

To copy from one path to another

```
$ cp file1 path1 path2
```

To copy in same directory

```
$ cp existing_file_name new_file_name
```

To rename a file or directory

```
$ mv file_name new_name
```

To display the beginning of a file

```
$ head file.txt
```

To display last part of a file

```
$ tail file.txt
```

To display the content of the file

```
$ cat file.txt
```

To copy the content in another file

```
$ cat file1.txt > file2.txt
```

To concatenate contents of different files in one single file

```
$ cat file1.txt file2.txt file3.txt > new_file.txt
```

To append the content of a file

```
$ cat >> file_name.txt
```

To display the content with their line numbers

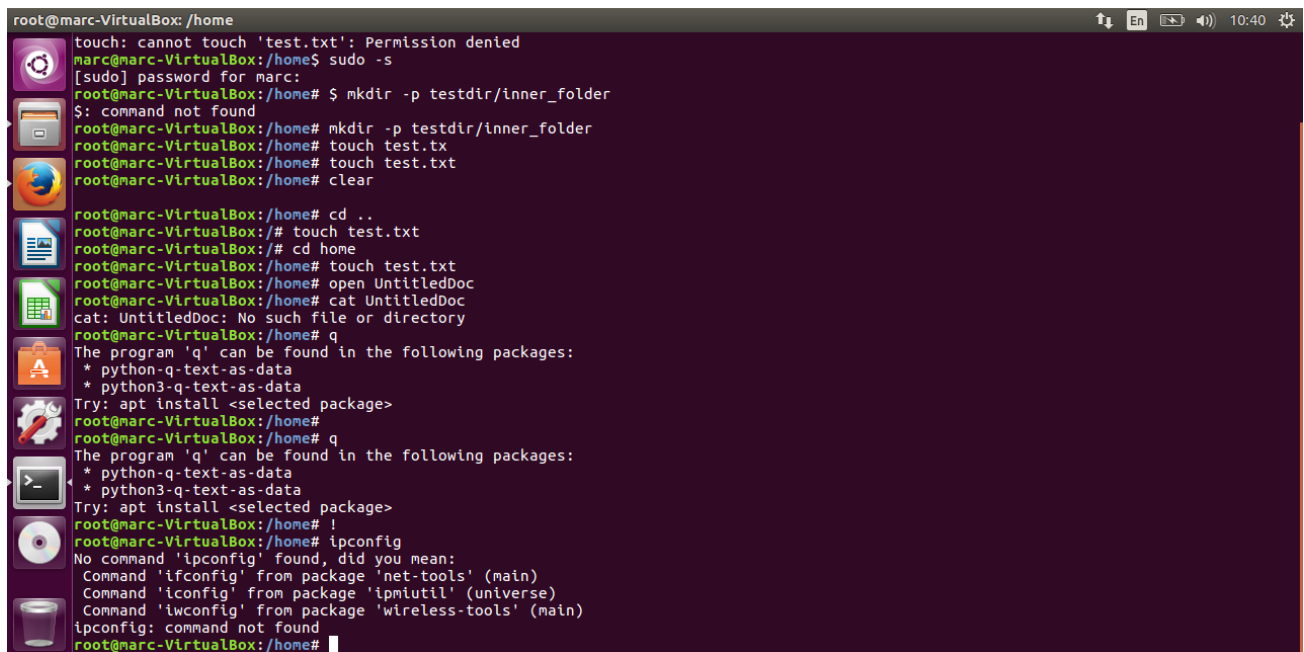

```
$ cat -n file_name.txt
```

To remove the empty lines form the file

```
$ cat -b file.txt
```

To display the end marker at the end of the file

```
$ cat > file.txt << end_marker_word
```

```
root@marc-VirtualBox: /home
touch: cannot touch 'test.txt': Permission denied
marc@marc-VirtualBox:/home$ sudo -s
[sudo] password for marc:
root@marc-VirtualBox:/home# $ mkdir -p testdir/inner_folder
$: command not found
root@marc-VirtualBox:/home# mkdir -p testdir/inner_folder
root@marc-VirtualBox:/home# touch test.tx
root@marc-VirtualBox:/home# touch test.txt
root@marc-VirtualBox:/home# clear

root@marc-VirtualBox:/home# cd ..
root@marc-VirtualBox:/# touch test.txt
root@marc-VirtualBox:/# cd home
root@marc-VirtualBox:/home# touch test.txt
root@marc-VirtualBox:/home# open UntitledDoc
cat: UntitledDoc: No such file or directory
root@marc-VirtualBox:/home# q
The program 'q' can be found in the following packages:
* python-q-text-as-data
* python3-q-text-as-data
Try: apt install <selected package>
root@marc-VirtualBox:/home#
root@marc-VirtualBox:/home# q
The program 'q' can be found in the following packages:
* python-q-text-as-data
* python3-q-text-as-data
Try: apt install <selected package>
root@marc-VirtualBox:/home# !
root@marc-VirtualBox:/home# ipconfig
No command 'ipconfig' found, did you mean:
Command 'ifconfig' from package 'net-tools' (main)
Command 'iconfig' from package 'ipmutil' (universe)
Command 'iwconfig' from package 'wireless-tools' (main)
ipconfig: command not found
root@marc-VirtualBox:/home#
```

PERMISSIONS OF THE FILES AND DIRECTORIES IN LINUX

Each file in Linux has attribute and have permissions of owner, Group and other.

"ls -l" OR "ls -la" will list the file and their details including permissions each file in

```
$ ls -l
$ ls -la
drwxr-xr-x  2 root root 4096 Jul  3 01:57 doc-base
drwxr-xr-x  2 root root 4096 Jul  3 01:57 dpkg
-rwxr--r--  1 root root    0 Aug  5 07:48 file_new.txt
```

"d" represent the directory and without d is the file. Here "drwxr-xr-x" and "-rw-r--r--" represent the permission of Owner, Group and Others in order:- read(r), write(w) and execute(x)

- first(1) represent the directory or file
- (2-4) i.e (rwx) in (-rwxrw-r--) and (rwx) in (drwxr-xr-x) represent the permission of file owner. Owner of the file have permission to read, write and execute.
- (5-7) i.e (rw-) in (-rwxrw-r--) represent the permission of the group to which this file belongs. Groups have permission only to read and write but not to execute.
- (8-10) i.e (r--) in (-rwxrw-r--) represent the permission for everyone. Everyone has the permission to read the file.

Changing the file permissions

Permission to a file is given by +/-/=

(+) is to add permission, (-) to remove permission and (==) to set the assigned permission

```
$ ls -l testfl
-rwxrw-r--  1 aarju  users 1024  Aug 2 00:10  testfl
```

Group have permission only to read and write this file but not to execute. Now to give permission to execute

```
$ chmod g+x testfl OR $ chmod 774 testfl
-rwxrwxr--  1 aarju  users 1024  Aug 2 00:15  testfl
```

To remove the execute permission from owner

```
$ chmod o-x testfl OR $ chmod 474 testfl
-rw-rwxr--  1 aarju  users 1024  Aug 2 00:20  testfl
```

Execute Permission is represented by number "1" and ref "--x"

Write Permission is represented by number "2" and ref "-w-"

Read permission is represented by number "4" and ref "--r"

To write and execute: 1+2 = 3 i.e "-wx"

To read and execute: 4+1 = 5 i.e "r-x"

To read and write: 4+2 = 6 i.e "rw-"

All permissions i.e to read, write and execute: 4+2+1 = 7 i.e "rwx"

```
ubuntu@ubuntu-VirtualBox: ~  
File Edit View Search Terminal Help  
To run a command as administrator (user "root"), use "sudo <command>".  
See "man sudo_root" for details.  
ubuntu@ubuntu-VirtualBox:~$ sudo chmod -R 755 /My/Folder
```
